KudiVault Data Story:

Prepared by Maryqueen Ayogu | Power BI dashboard review (3 pages)

All figures below are read from the Power BI dashboard screenshots and cross-checked against the KudiVault 2.0 presentation deck.

The project

KudiVault 2.0 is the relaunch of a Nigerian fintech savings app, presented by a product team covering product management, data analysis, cybersecurity and digital marketing. The deck shows 1,000 users and 9,223 successful transactions. My part was cleaning the data and building the three-page Power BI dashboard: KPI Overview, Transaction and Security, and Marketing and Retention.

The business problem

Users start the journey but do not consistently finish it. The deck names seven challenges: low user trust, onboarding drop-off, low first deposits, failed transactions, security concerns, poor retention and weak marketing performance.

The product question was: how do we move users from sign-up to successful saving with confidence? The dashboard had to show where users drop off, where money and trust are at risk, and which marketing spend works.

Data, tools and cleaning

I built the model in Power BI with Excel for preparation and DAX for the measures. The tables are Activity, Churn Retention, Funnel Stages, Marketing, Security, Target Table, Transactions, Users and the date tables. Trustworthy decisions needed trustworthy numbers, so I cleaned the data before any visual was built.

Issue found	Records affected	Treatment
Duplicate user rows	8	Removed
Duplicate transaction rows	20	Removed
Missing transaction status	12	Flagged as a server-side bug
Missing session time and notification click rate	53	Flagged as an app-level bug
Extreme transaction amounts	8	Identified and analysed on the Security page
Active vs churn status inconsistencies	68	Resolved

Issue found	Records affected	Treatment
Signup-step misallocations	50	Corrected
KYC-step misallocations	108	Corrected
Missing monthly income range	about 4% of rows	Cleaned
Missing location	about 2% of rows (20 users)	Cleaned
Casing inconsistencies in signup channel, location and channel	small subset	Cleaned

Open question: add the exact fix for the last three rows (Power Query, Excel or DAX, and what blanks became), so the README is specific.

What the dashboards solved

The three pages answer one chain of questions: where do users drop off, can they transact safely, and which marketing works. The findings for each page follow.

Page 1: KPI Overview

Questions it answers

- How many users are active, onboarded and saving?
- Are we hitting our KPI targets?

Observations

- MAU is 963, current active users are 904, and 988 users save on a recurring basis.
- KYC completion is 719 users (0.72 against a 0.80 target) and bank linking is 93 users (0.09 against 0.80), so bank linking is the biggest gap.
- The total 30-day savings balance is ₦2.37M and there were 9.22K successful transactions.
- MAU (0.96 against 0.70) and successful transactions (0.89 against 0.50) are above target.

Recommendations

- Make bank linking mandatory with guided onboarding.
- Run a KYC push over Push, Email and SMS to close the 8-point gap.

Page 2: Transaction and Security

Questions it answers

- Which payment methods fail most?
- Are outlier transactions a risk?
- Do IP mismatch, device switching, failed logins and MFA line up with fraud risk?

Observations

- Bank Transfer carries most of the volume (5.7K successful, 0.4K failed), followed by Card (2.3K, 0.2K) and USSD (1.2K, 0.1K).
- The outlier chart shows ₦292.79K against ₦15.79K for normal transactions, so outliers are about 18.5x larger, not 20x. It looks like an average amount, so check the measure.
- Flagged users score 2.03 on device switching against 0.59 for non-flagged users, about 3.4x higher.
- Suspicious activity is 28.81% when the IP mismatches and 9.35% when it matches, about 3x higher.
- Failed logins rise with risk level: Escalated 3.33, Monitored 2.78, Clear 1.34.
- 592 users have MFA and 408 don't, which matches the deck's 59% and 40.8%. 39 flagged users (26 Monitored plus 13 Escalated) have no MFA, which also matches the deck.
- MFA alone doesn't separate flagged from clear users. About 62-64% of Monitored and Escalated users have MFA, against 59% of Clear users.

Recommendations

- Investigate Bank Transfer failures first.
- Add review limits and authorization for outlier amounts.
- Use risk-based authentication triggered by IP mismatch, device switching and repeated failed logins, not just MFA.
- Push MFA toward the 70%+ target, starting with the 39 flagged users who lack it.

Page 3: Marketing and Retention

Questions it answers

- Which channels, campaigns and creative themes convert cheapest?
- How are users split by retention bucket?
- Where are users located?

Observations

- By channel, Push, Email and SMS cost about ₦0.4K per conversion. TikTok is ₦1.5K, X ₦1.6K and Instagram ₦1.8K.
- By campaign type, Reactivation is cheapest (₦676.74) and Rate Promo is most expensive (₦862.57).
- By creative theme, Save Smarter is cheapest (₦615.89) and Beat Inflation is most expensive (₦928.96).
- Retention buckets split 359 (35.9%), 350 (35%), 285 (28.5%) and 6 (0.6%). The 285 slow-conversion users are the main opportunity.
- 904 users (90.4%) are not churned and 96 (9.6%) are.
- Lagos has 283 users, about 3x Abuja (90). Port Harcourt (86), Benin City (81), Enugu (81) and Ibadan (81) follow closely.
- The location chart adds up to 980 users out of 1,000. The missing 20 (2%) match the "missing location on ~2% of rows" issue, which shows how the data cleaning appears in the dashboard.

Recommendations

- Move budget to Push, Email and SMS, and keep TikTok and X for limited reactivation.
- Scale Save Smarter and Reactivation messaging, and rework Beat Inflation.
- Study what the fast converters did and use it to shrink the slow-conversion group.
- Target the 96 churned users with a reactivation campaign.
- Test acquisition in the cities close behind Abuja, to see whether Lagos dominance is market size or acquisition.

Overall recommendations

The data points to one objective: get more users safely through activation, then keep them saving.

1. **Fix onboarding first.** Make KYC a priority (71.9%) and bank linking mandatory (9.3%).
2. **Make transactions reliable.** Success is 87.62% against a target near 95%, with Bank Transfer failing most.
3. **Secure the journey.** Enforce MFA and use risk signals (IP mismatch, device switching, failed logins) to catch fraud.
4. **Spend where it converts.** Move budget to Push, Email and SMS, which cost 4-5x less per conversion than paid social.
5. **Build on strong saving behaviour.** 988 users already save on a recurring basis, so the opportunity is getting more users to that point.
